Elephant

Amoeba

The cell was discovered by <u>Robert Hooke</u> in 1665

Anatomy

.

There are two types of cells: eukaryotic and prokaryotic. Prokaryotic cells are usually independent, while eukaryotic cells are often found in multicellular organisms.

Prokaryotic cells

Main article: <u>Prokaryote</u>

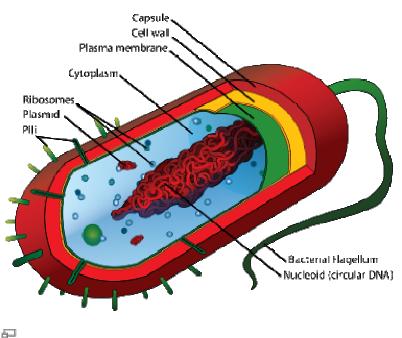

Diagram of a typical <u>prokaryotic</u> cell

The <u>prokaryote</u> cell is simpler, and therefore smaller, than a eukaryote cell, lacking a <u>nucleus</u> and most of the other <u>organelles</u> of eukaryotes. There are two kinds of prokaryotes: <u>bacteria</u> and <u>archaea</u>; these share a similar structure.

Nuclear material of prokaryotic cell consist of a single chromosome that is in direct contact with cytoplasm. Here, the undefined nuclear region in the cytoplasm is called <u>nucleoid</u>.

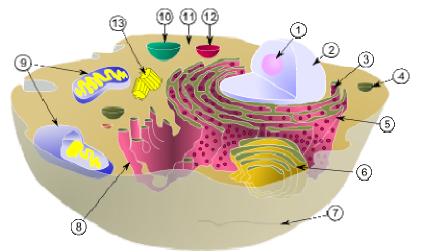

A prokaryotic cell has three architectural regions:

- On the outside, <u>flagella</u> and <u>pili</u> project from the cell's surface. These are structures (not present in all prokaryotes) made of proteins that facilitate movement and communication between cells;
- Enclosing the cell is the <u>cell envelope</u> generally consisting of a <u>cell wall</u> covering a <u>plasma membrane</u> though some bacteria also have a further covering layer called a <u>capsule</u>. The envelope gives rigidity to the cell and separates the interior of the cell from its environment, serving as a protective filter. Though most prokaryotes have a cell wall, there are exceptions such as <u>Mycoplasma</u> (bacteria) and <u>Thermoplasma</u> (archaea). The cell wall consists of <u>peptidoglycan</u> in bacteria, and acts as an additional barrier against exterior forces. It also prevents the cell from expanding and finally bursting (<u>cytolysis</u>) from <u>osmotic pressure</u> against a <u>hypotonic</u> environment. Some eukaryote cells (<u>plant cells</u> and <u>fungi</u> cells) also have a cell wall;
- Inside the cell is the <u>cytoplasmic region</u> that contains the <u>cell genome</u> (DNA) and ribosomes and various sorts of inclusions. A <u>prokaryotic chromosome</u> is usually a circular molecule (an exception is that of the bacterium <u>Borrelia burgdorferi</u>, which causes Lyme disease). Though not forming a *nucleus*, the <u>DNA</u> is condensed in a

nucleoid. Prokaryotes can carry <u>extrachromosomal DNA</u> elements called <u>*plasmids*</u>, which are usually circular. Plasmids enable additional functions, such as <u>antibiotic resistance</u>.

Eukaryotic cells

Main article: Eukaryote

Ð

Diagram of a typical <u>animal</u> (<u>eukaryotic</u>) cell, showing subcellular components. <u>Organelles</u>:

- (1) <u>nucleolus</u>
- (2) <u>nucleus</u>
- (3) <u>ribosome</u>
- (4) <u>vesicle</u>
- (5) rough endoplasmic reticulum (ER)
- (6) <u>Golgi apparatus</u>
- (7) <u>Cytoskeleton</u>
- (8) smooth endoplasmic reticulum
- (9) mitochondria
- (10) <u>vacuole</u>
- (11) cytoplasm
- (12) lysosome
- (13) centrioles within centrosome

<u>Eukaryotic</u> cells are about 15 times wider than a typical prokaryote and can be as much as 1000 times greater in volume. The major difference between prokaryotes and eukaryotes is that eukaryotic cells contain membrane-bound compartments in which specific metabolic activities take place. Most important among these is a <u>cell nucleus</u>, a membrane-delineated compartment that houses the eukaryotic cell's DNA. This nucleus gives the eukaryote its name, which means "true nucleus." Other differences include:

- The plasma membrane resembles that of prokaryotes in function, with minor differences in the setup. Cell walls may or may not be present.
- The eukaryotic DNA is organized in one or more linear molecules, called <u>chromosomes</u>, which are associated with <u>histone</u> proteins. All chromosomal DNA is stored in the <u>cell</u>

nucleus, separated from the cytoplasm by a membrane. Some eukaryotic <u>organelles</u> such as <u>mitochondria</u> also contain some DNA.

- Many eukaryotic cells are <u>ciliated</u> with *primary cilia*. Primary cilia play important roles in chemosensation, <u>mechanosensation</u>, and thermosensation. Cilia may thus be "viewed as sensory cellular <u>antennae</u> that coordinate a large number of cellular signaling pathways, sometimes coupling the signaling to ciliary motility or alternatively to cell division and differentiation."^[7]
- Eukaryotes can move using *motile <u>cilia</u>* or *flagella*. The flagella are more complex than those of prokaryotes.
